Project Title: Script-Controlled ACL – Restrict Record Access Based on Field Value

Date: 30 September 2026

Team ID: _____

Project Name: Script-Controlled ACL – Restrict Record Access Based on Field Value

Maximum Marks: 4 Marks

Project Overview

The project focuses on implementing a script-controlled Access Control List (ACL) that restricts access to records according to the value of a selected field. The objective is to provide controlled, field-based record visibility so that users can access only the records permitted by the defined business rule.

Step-1: Team Gathering, Collaboration and Select the Problem Statement

The team identifies the problem of unrestricted or overly broad record access in an application. A script-controlled ACL is selected as the solution because access can be evaluated dynamically using a record field value.

Problem Statement: Users should not be able to access every record. Record access must be restricted when the value of a specified field does not satisfy the defined access condition.

Proposed Solution: Create a scripted ACL that checks a field value on the record and grants or denies access based on the result of the script.

Step-2: Brainstorm, Idea Listing and Grouping

Idea	Purpose	Expected Result
Field-value validation	Check the selected field before allowing access.	Only records meeting the condition are accessible.
Scripted ACL condition	Use a script to dynamically evaluate the record.	Access is granted or denied automatically.
Role/user verification	Combine field value with the current user's access context.	Unauthorized users are prevented from viewing restricted records.
Access testing	Test allowed and denied cases.	The ACL behaves consistently for different record values.

Step-3: Idea Prioritization

The ideas are prioritized according to their relevance to the main objective: restricting record access based on a field value.

Priority Area	Reason	Priority
Field-value validation	Core requirement for record restriction.	High
Scripted ACL condition	Provides dynamic access control.	High
Access testing	Confirms correct behavior for permitted and restricted records.	High

Role/user verification	Can provide an additional layer of authorization.	Medium

Proposed ACL Workflow

1. User requests access to a record.

2. The ACL is triggered for the requested operation.

3. The script reads the relevant field value from the record.

4. The field value is compared with the defined access condition.

5. If the condition is satisfied, access is allowed.

6. If the condition is not satisfied, access is denied.

ALLOW ACCESS / DENY ACCESS

Expected Outcome

The system should enforce record-level access according to the selected field value. Records satisfying the ACL condition should be accessible, while records that fail the condition should be restricted.

Conclusion

Script-controlled ACL provides a flexible method for implementing field-based record access. By validating a record field through a script, the project can enforce consistent and dynamic access restrictions while supporting the application's security requirements.
